

Support Vector Machines (SVM) is a type of supervised learning techniques that analyze data to make predictions.

- **Supervised Data:** The data that indicate two set of features namely, indicator variables and predictive variable (class variable).
- **Indicator variables** are the set of variables that are used to forecast the predictive variable.

Since support vector machines (SVM) is a type of supervised learning techniques, the information about class variable is prerequisite.

SVM tries to separate the different types of classes using decision boundary.

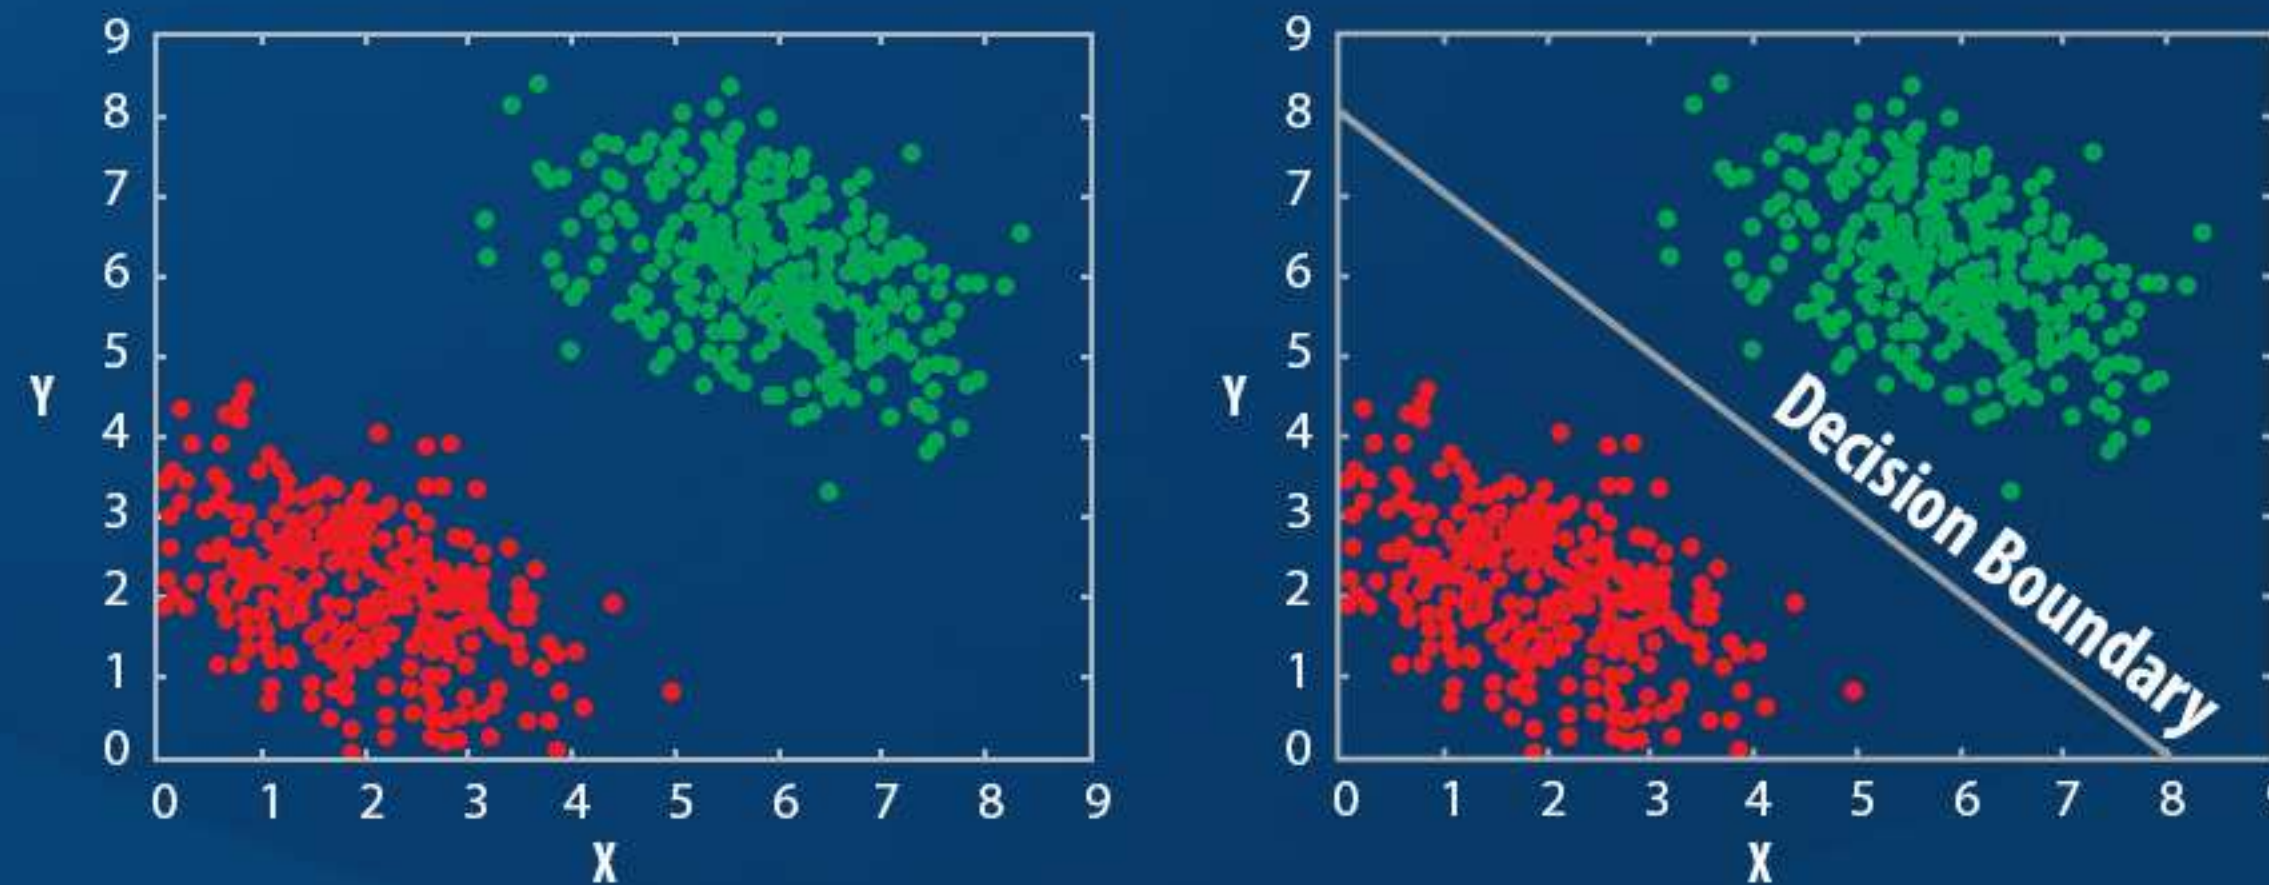

OBJECTIVE OF SUPPORT VECTOR MACHINES

- Support Vector Machines (SVM) is a kind of supervised technique used to make predictions.
- Let's understand SVM with a very simple example.

Example

Let us consider that we are given two sets of objects: Red and Green, and our data has two features: X and Y.

We want a classifier that, given a pair of (X,Y) coordinates, outputs if it is either **Red** or **Green**. We plot our already labeled training data on a plane:

- Based on the decision boundary learnt by the model, a new case is tested if its below decision boundary or above decision boundary.
- In case, data point is above decision boundary, the label is **Green** class whereas, in another case, it is treated as belonging to **Red** class.

SUPPORT VECTOR MACHINES - BASIC TERMINOLOGY AND MATHEMATICS I

Introduction to Line, Plane and Hyperplane

1. Line

Line divides area in 2 parts only in 2-dimensional

2. Plane

Plane divides area in 3-dimensional.

3. Hyperplane

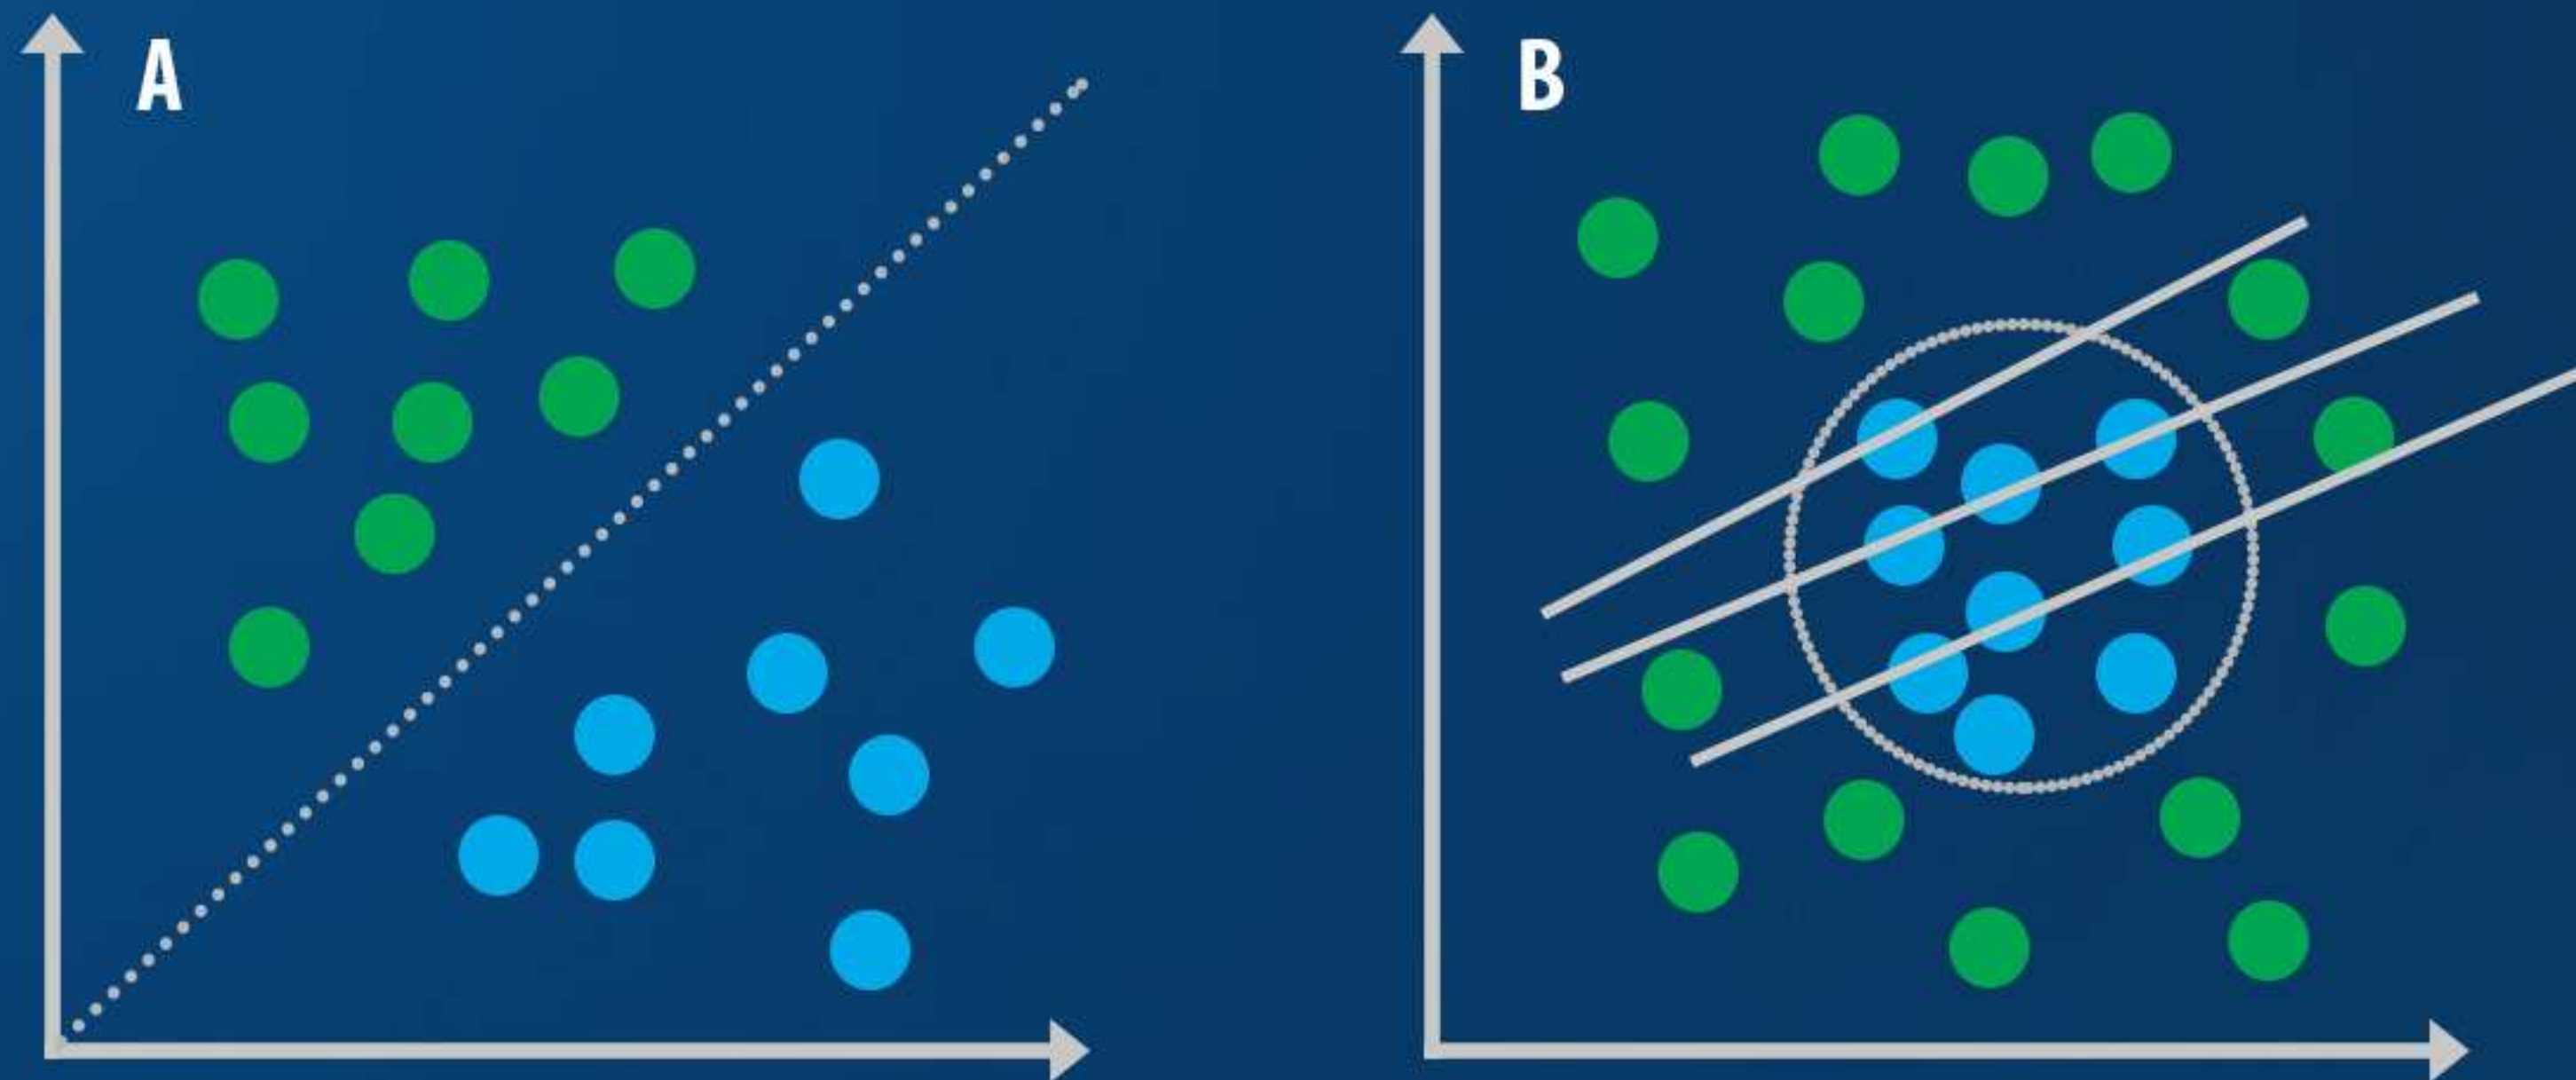

Hyperplane divides area in high dimensional architecture.

$$W_0 + W_1x_1 + W_2x_2 + \dots + W_nx_n = 0$$

$$W_0 + \sum_{i=1}^n W_i x_i = 0$$
